EXAM AWS CERTIFIED DEVELOPER - ASSOCIATE DVA-C02 TOPIC 1 QUESTIO...

Exam question from Amazon's AWS Certified Developer - Associate DVA-C02
Question #: 2
Topic #: 1
[All AWS Certified Developer - Associate DVA-C02 Questions]

A company is running Amazon EC2 instances in multiple AWS accounts. A developer needs to implement an application that collects all the lifecycle events of the EC2 instances. The application needs to store the lifecycle events in a single Amazon Simple Queue Service (Amazon SQS) queue in the company's main AWS account for further processing.
Which solution will meet these requirements?

A. Configure Amazon EC2 to deliver the EC2 instance lifecycle events from all accounts to the Amazon EventBridge event bus of the main account. Add an EventBridge rule to the event bus of the main account that matches all EC2 instance lifecycle events. Add the SQS queue as a target of the rule.

B. Use the resource policies of the SQS queue in the main account to give each account permissions to write to that SQS queue. Add to the Amazon EventBridge event bus of each account an EventBridge rule that matches all EC2 instance lifecycle events. Add the SQS queue in the main account as a target of the rule.

C. Write an AWS Lambda function that scans through all EC2 instances in the company accounts to detect EC2 instance lifecycle changes. Configure the Lambda function to write a notification message to the SQS queue in the main account if the function detects an EC2 instance lifecycle change. Add an Amazon EventBridge scheduled rule that invokes the Lambda function every minute.

D. Configure the permissions on the main account event bus to receive events from all accounts. Create an Amazon EventBridge rule in each account to send all the EC2 instance lifecycle events to the main account event bus. Add an EventBridge rule to the main account event bus that matches all EC2 instance lifecycle events. Set the SQS queue as a target for the rule.

Untamables Highly Voted 3 years ago

Selected Answer: D

The correct answer is D.
Amazon EC2 instances can send the state-change notification events to Amazon EventBridge.
https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/monitoring-instance-state-changes.html
Amazon EventBridge can send and receive events between event buses in AWS accounts.
https://docs.aws.amazon.com/eventbridge/latest/userguide/eb-cross-account.html

Selected Answer: D

Answer is D.
Amazon EC2 sends an EC2 Instance State-change Notification event to Amazon EventBridge when the state of an instance changes.

Selected Answer: C

Either C or D. Down side of C: Needs to trigger everyone min but very flexible. D: is completely automated but giving access to other aws account is not safe.

A) Eliminated - Amazon EC2 itself does not send lifecycle events directly to EventBridge in another account. The EC2 lifecycle events would be published to EventBridge within the account where the EC2 instance resides.

The key here is using EventBridge cross-account event bus access. Amazon EventBridge allows for event buses to receive events from other AWS accounts if the appropriate permissions are set.

B) Will work as Option B is implying a direct route from each AWS account's EventBridge to the main account's SQS queue, bypassing the main account's EventBridge event bus - Eliminated - as No centralized events, which is in Option D

upvoted 1 times

sumanshu 1 year, 3 months ago

C) Eliminated - more maintenance overhead of LAMBDA

upvoted 1 times

trieudo 1 year, 3 months ago

Selected Answer: D

==> Discard C: lamdba scans ==> it will be delay by scan all data
==> Discard A: 'matches all EC2 instance' ==> hard to maintain, when updating many times can occurs
==> Discard B: it works, but it maybe have some security problem when pushing raw data (not clean) into SQS. It also doesn't take advantage of

D: By configuring the main account's event bus to accept events from other accounts and adding rules in those accounts to forward lifecycle events, this solution achieves secure and efficient centralization. EventBridge then routes the events to an SQS queue in the main account for further processing.

Selected Answer: D

Tried to implement both B and D
It's tricky, because B could be possible but you can't select cross-account SQS as target to the rule, option D is 100% correct

Selected Answer: B

Seems to me the correct answer is B. The current most voted answer is B, but can someone explain why it’s better than B? I think B is better because it has fewer steps. The events go straight from each account into the queue. Unlike in D which has the intermediate step of the event bus of the main account. Also, why would you want to pollute the event bus of the main account with events from other accounts when it isn’t necessary?

upvoted 5 times

KillThemWithKindness 2 years, 8 months ago

B
Answer A is incorrect because Amazon EventBridge events can't be sent directly from one account's event bus to another.

Answer C is incorrect because it's unnecessary and inefficient to use Lambda to periodically scan all EC2 instances for lifecycle changes. Amazon EventBridge can capture these events automatically as they occur.

Answer D is incorrect because it is not possible to configure the main account event bus to receive events from all accounts directly, and Amazon EventBridge events can't be sent directly from one account's

event bus to another. The EventBridge rules need to be set up in the accounts where the events are generated.

Sorry Im wrong, AWS allow to send and receive Amazon EventBridge events between AWS accounts.
https://docs.aws.amazon.com/eventbridge/latest/userguide/eb-cross-account.html

Both B and D works, but D is more centralized

Selected Answer: A

Option D is not the best solution because it involves configuring the permissions on the main account's EventBridge event bus to receive events from all accounts, which can lead to potential security risks. Allowing other AWS accounts to send events to the main account's EventBridge event bus can potentially open up a security vulnerability, as it increases the attack surface area for the main account.

On the other hand, option A is the best solution because it involves using Amazon EventBridge, which is a serverless event bus that can be used to route events between AWS services or AWS accounts. By configuring Amazon EC2 to deliver the EC2 instance lifecycle events from all accounts to the Amazon EventBridge event bus of the main account, and adding the SQS queue as a target of the rule, the application can collect all the lifecycle events of the EC2 instances in a single queue in the main account without compromising the security posture of the AWS environment.
