EXAM AWS CERTIFIED DEVELOPER - ASSOCIATE DVA-C02 TOPIC 1 QUESTIO...

Exam question from Amazon's AWS Certified Developer - Associate DVA-C02
Question #: 69
Topic #: 1
[All AWS Certified Developer - Associate DVA-C02 Questions]

A developer is configuring an application's deployment environment in AWS CodePipeline. The application code is stored in a GitHub repository. The developer wants to ensure that the repository package's unit tests run in the new deployment environment. The developer has already set the pipeline's source provider to GitHub and has specified the repository and branch to use in the deployment.

Which combination of steps should the developer take next to meet these requirements with the LEAST overhead? (Choose two.)

A. Create an AWS CodeCommit project. Add the repository package's build and test commands to the project's buildspec.

B. Create an AWS CodeBuild project. Add the repository package's build and test commands to the project's buildspec.

C. Create an AWS CodeDeploy project. Add the repository package's build and test commands to the project's buildspec.

D. Add an action to the source stage. Specify the newly created project as the action provider. Specify the build artifact as the action's input artifact.

E. Add a new stage to the pipeline after the source stage. Add an action to the new stage. Specify the newly created project as the action provider. Specify the source artifact as the action's input artifact.

The correct answer is B and E
The buildspec file is a collection of build commands and related settings, in YAML format, that CodeBuild uses to run a build. By adding the build and test commands to the buildspec file, the developer can ensure that these commands are executed as part of the build process. Option E will ensure that the CodeBuild project is triggered as part of the pipeline and that the unit tests are run in the new deployment environment.

Selected Answer: BE

For those who just skim the question, keyword between D and E is "unit tests run in the new deployment environment.", which signifies a new stage should be created instead of just adding an action.

Selected Answer: BE

AWS CodeBuild is specifically designed for building and testing code in CI/CD pipelines. The buildspec file is where the developer can specify commands to build and run unit tests for the application package.

A new stage after the source stage ensures that the unit tests run on the package retrieved from GitHub.

E. Add a new stage to the pipeline after the source stage: This is the correct step. The developer should add a new stage to the pipeline specifically for building and testing the code. Within this stage, an action should be added that specifies the AWS CodeBuild project (created in step B) as the action provider. The source artifact (code fetched from GitHub) should be specified as the action's input artifact.

So, the combination of steps that should be taken next to meet these requirements with the least overhead are:

B. Create an AWS CodeBuild project. Add the repository package's build and test commands to the project's buildspec.

E. Add a new stage to the pipeline after the source stage. Add an action to the new stage. Specify the newly created CodeBuild project as the action provider. Specify the source artifact as the action's input artifact.

Selected Answer: BD

Choosing D as that is the least overhead. There is already a stage and you need to add an action test

Sorry will go with BE after ding more research as unit tests cannot be run in source stage as an action
