EXAM AWS CERTIFIED AI PRACTITIONER AIF-C01 TOPIC 1 QUESTION 14 DIS...

Exam question from Amazon's AWS Certified AI Practitioner AIF-C01

Question #: 14

Topic #: 1

[All AWS Certified AI Practitioner AIF-C01 Questions]

A company wants to develop an educational game where users answer questions such as the following: "A jar contains six red, four green, and three yellow marbles. What is the probability of choosing a green marble from the jar?"

Which solution meets these requirements with the LEAST operational overhead?

A. Use supervised learning to create a regression model that will predict probability.

B. Use reinforcement learning to train a model to return the probability.

C. Use code that will calculate probability by using simple rules and computations.

D. Use unsupervised learning to create a model that will estimate probability density.

Selected Answer: C

C: Use code that will calculate probability by using simple rules and computations.

Explanation:
For a question like this, where the probability can be computed using basic arithmetic (e.g., number of favorable outcomes divided by total outcomes), implementing a straightforward function in code will meet the requirements with the least operational overhead. This avoids the complexity and resource demands of machine learning.

For example:

Total marbles =
6
+
4
+
3
=
13
6+4+3=13

Selected Answer: C

C is the correct answer.

Selected Answer: C

Estimated Costs
Memory: Less than 1 MB for the model.
Computation: A few seconds to minutes on a standard laptop CPU.
Data: A few hundred examples, which can be generated programmatically.
Instead

```
def calculate_probability(green_marbles, total_marbles):
return green_marbles / total_marbles

# Example usage
green_marbles = 4
total_marbles = 6 + 4 + 3 # red + green + yellow
probability = calculate_probability(green_marbles, total_marbles)
print(f"Probability of choosing a green marble: {probability:.2f}")
```

A program is effective and time saving

Selected Answer: C

The problem described is a simple probability calculation based on basic combinatorics. The probability of choosing a green marble is simply the ratio of green marbles to total marbles, which can be computed directly without needing a complex machine learning model.
Using a straightforward code implementation to calculate the probability based on the given numbers (6 red, 4 green, and 3 yellow marbles) will

be the most efficient and have the least operational overhead. It's a direct computation using basic arithmetic.

Selected Answer: C

Make it simple : Use code that will calculate probability by using simple rules and computations.

Selected Answer: C

Not necessary to train a model for this. Code for computation is sufficient.
