EXAM AWS CERTIFIED DEVELOPER - ASSOCIATE DVA-C02 TOPIC 1 QUESTIO...

Exam question from Amazon's AWS Certified Developer - Associate DVA-C02
Question #: 147
Topic #: 1
[All AWS Certified Developer - Associate DVA-C02 Questions]

A developer is building an application that gives users the ability to view bank accounts from multiple sources in a single dashboard. The developer has automated the process to retrieve API credentials for these sources. The process invokes an AWS Lambda function that is associated with an AWS CloudFormation custom resource.

The developer wants a solution that will store the API credentials with minimal operational overhead.

Which solution will meet these requirements in the MOST secure way?

A. Add an AWS Secrets Manager GenerateSecretString resource to the CloudFormation template. Set the value to reference new credentials for the CloudFormation resource.

B. Use the AWS SDK ssm:PutParameter operation in the Lambda function from the existing custom resource to store the credentials as a parameter. Set the parameter value to reference the new credentials. Set the parameter type to SecureString.

C. Add an AWS Systems Manager Parameter Store resource to the CloudFormation template. Set the CloudFormation resource value to reference the new credentials. Set the resource NoEcho attribute to true.

D. Use the AWS SDK ssm:PutParameter operation in the Lambda function from the existing custom resource to store the credentials as a parameter. Set the parameter value to reference the new

credentials. Set the parameter NoEcho attribute to true.

Comments

Jing2023 Highly Voted 2 years, 5 months ago

Answer is B
A is not correct as the requirement asked to store API credentials, GenerateSecretString will create a random string as password.
C the API credential will be retrieved by the Lambda function, it is un-available to the template.
D no echo is a attribute of cloud formation template.

Selected Answer: D

The correct answer is (D).

Solution (D) is the most secure because it stores the API credentials in AWS Secrets Manager, which is a managed service that provides secure, policy-controlled storage for secrets. The parameter's NoEcho attribute prevents the parameter value from being displayed in the console or request history.

Selected Answer: B

SecureString parameters are encrypted both when stored in the Parameter Store (at rest) and while being transmitted (in transit) using AWS KMS (Key Management Service). This means that even if someone were to gain unauthorized access to the Parameter Store's underlying storage, they wouldn't be able to easily read the parameter's value.

Selected Answer: C

I choose C, not choose A due to minimal cost
I dont understand why most of you choose B

upvoted 2 times

ShakthiGCP 1 year, 5 months ago

NoEcho is not very secure compared to SecureString which encrypts the sensitive data at rest and transit.

Selected Answer: A

I will got with A.
Becausehttps://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/parameters-section-structure.html nullifying the B&D. Justifying A https://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/dynamic-references.html

Selected Answer: B

The solution that will meet the requirements is to use the AWS SDK ssm PutParameter operation in the Lambda function from the existing custom resource to store the credentials as a parameter. Set the parameter value to reference the new credentials. Set the parameter type to SecureString. This way, the developer can store the API credentials with minimal operational overhead, as AWS Systems Manager Parameter Store provides secure and scalable storage for configuration data. The SecureString parameter type encrypts the parameter value with AWS Key Management Service (AWS KMS). The other options either involve adding additional resources to the CloudFormation template, which increases complexity and cost, or do not encrypt the parameter value, which reduces security.

Selected Answer: B

B. Use the AWS SDK ssm:PutParameter operation in the Lambda function from the existing custom resource to store the credentials as a parameter. Set the parameter value to reference the new credentials. Set the parameter type to SecureString: This is a secure and operationally

efficient solution. AWS Systems Manager Parameter Store can securely store parameters as SecureString, which encrypts the parameter value. The ssm:PutParameter operation can be used within the Lambda function to store the credentials directly after retrieval, minimizing operational overhead.

Is B the correct answer?
SecureString isn't currently supported for AWS CloudFormation templates.
