EXAM AWS CERTIFIED AI PRACTITIONER AIF-C01 TOPIC 1 QUESTION 105 DI...

Exam question from Amazon's AWS Certified AI Practitioner AIF-C01

Question #: 105

Topic #: 1

[All AWS Certified AI Practitioner AIF-C01 Questions]

A company wants to use large language models (LLMs) to produce code from natural language code comments.

Which LLM feature meets these requirements?

A. Text summarization

B. Text generation

C. Text completion

D. Text classification

Selected Answer: C

The requirement is to produce code from natural language code comments. This is a classic code completion use case, where the model continues existing text (comments) by generating the corresponding code.

Why Text completion is correct:

Takes a prompt or partial text (for example, comments)

Generates the most likely continuation (the code)

Commonly used in IDEs for code generation from comments

Why the other options are incorrect:

A. Text summarization ❌

Condenses text instead of generating new content

Selected Answer: C

Text completion is the LLM capability that continues or completes text based on existing context. The natural language code comments provide context. The model completes that context by generating the corresponding code

This is exactly how many code assistants work: they read comments or partial code and complete it with valid code.

Selected Answer: C

C. Text completion ✅
Explanation:
- Text completion allows an LLM to predict and generate the next part of text based on a given prompt.
- In this scenario, the prompt is a natural language code comment, and the model completes it by generating the corresponding code.

B (Text generation) → A broader category, but text completion specifically fits “produce code from a prompt.”

Selected Answer: B

B. Text Generation.

A Text Summarisation is wrong because code is not a summary of the comment. If it was, it would be shorter, and code is often, longer.

B. Text completion is wrong, because text completion is where you start to write a sentence and it completes the last word. That's not what's happening here, as we're converting one type of storage of an idea (a comment) into a different type of storage of the idea (code).

D Text classification is wrong because we're not classifying text into groups.

Selected Answer: C

The LLM feature that meets the requirement of producing code from natural language code comments is C. Text completion.
Explanation:
Text completion is the ability of an LLM to generate the most likely continuation of a given input. In this case, the input is the natural language code comment, and the model needs to generate the corresponding code. This aligns perfectly with how text completion works, as it predicts the next sequence of tokens based on the provided context.

Selected Answer: C

The task described — producing code from natural language comments — involves continuing or completing a prompt (in this case, natural language) with appropriate code. This is best handled by the text completion capability of large language models (LLMs).

You provide a prompt such as:

This function calculates the factorial of a number\n def factorial(n):

The model completes the rest with actual code.

Text completion is specifically designed for this kind of task, where the model infers the most likely continuation of a given input, which can be natural language or code.

Selected Answer: B

Large language models (LLMs) that convert natural language comments into code need the ability to generate new content based on the provided input. This aligns with the text generation feature, where the

model produces human-like text, including writing code from natural language descriptions.

Selected Answer: B

The correct answer is B. Text generation is the appropriate feature for converting natural language into code.

Selected Answer: B

To produce code from natural language code comments, text generation is the appropriate feature of an LLM.
