EXAM AWS CERTIFIED DEVELOPER - ASSOCIATE DVA-C02 TOPIC 1 QUESTIO...

Exam question from Amazon's AWS Certified Developer - Associate DVA-C02
Question #: 550
Topic #: 1
[All AWS Certified Developer - Associate DVA-C02 Questions]

A developer is building an application that stores sensitive user data. The application includes an Amazon CloudFront distribution and multiple AWS Lambda functions that handle user requests.

The user requests contain over 20 data fields. Each application transaction contains sensitive data that must be encrypted. Only specific parts of the application need to have the ability to decrypt the data.

Which solution will meet these requirements?

A. Associate the CloudFront distribution with a Lambda@Edge function. Configure the function to perform field-level asymmetric encryption by using a user-defined RSA public key that is stored in AWS Key Management Service (AWS KMS).

B. Integrate AWS WAF with CloudFront to protect the sensitive data. Use a Lambda function and self-managed keys to perform the encryption and decryption processes.

C. Configure the CloudFront distribution to use WebSockets by forwarding all viewer request headers to the origin. Create an asymmetric AWS KMS key. Configure the CloudFront distribution to use field-level encryption. Use the AWS KMS key.

D. Configure the cache behavior in the CloudFront distribution to require HTTPS for communication between viewers and CloudFront. Configure GoudFront to require users to access the files by using either signed URLs or signed cookies.

Selected Answer: A

Answer is A

C not correct :
CloudFront does support field-level encryption, but it does not use AWS KMS keys directly for this. Instead, it uses its own mechanism with public keys you upload.

Selected Answer: C

Field-level encryption allows specific fields in user requests to be encrypted while leaving other fields readable.

Encryption is performed at the edge (CloudFront), ensuring data is protected before reaching the application backend.
