Selected Answer: B

B: Transcribe call recordings by using Amazon Transcribe.

Explanation:
Amazon Transcribe is designed for converting speech in audio files (such as customer calls) into text. This text can then be analyzed further to extract key information. It is the first step in gaining insights from audio conversations, making it the appropriate solution for the given requirement.

Selected Answer: D

Changing my answer to D: "Amazon Comprehend is a natural language processing (NLP) service that uses machine learning to extract insights and information from text. It can identify key elements like entities (people, places, organizations), phrases, sentiment, and language, and is used for tasks such as voice of the customer analytics, semantic search, and knowledge discovery."

Selected Answer: B

Amazon Transcribe is a service designed to automatically convert audio (such as customer call recordings) into text. Once transcribed, the text can be further processed to extract key insights, such as customer intent, sentiment, and specific information (e.g., product details or requests). This aligns directly with the goal of analyzing and extracting key information from customer conversations.

select B

Amazon Transcribe is a service that converts audio into text, making it ideal for transcribing customer calls in a contact center. Once the audio is transcribed into text, you can further analyze the transcribed text to gain insights, such as identifying key information, customer sentiment, and specific topics discussed during the conversation.

Udyan 1 year, 4 months ago

Amazon Transcribe is designed specifically to convert audio to text, which is a necessary first step for gaining insights from customer conversations. Once transcribed, the text data can be further processed and analyzed for key information.

Amazon Comprehend (option D) is useful for extracting insights from text, like sentiment analysis and entity extraction, but it only works on text data, not on audio files directly. So, Amazon Comprehend could be used after Amazon Transcribe has converted the audio to text, but it wouldn't be a standalone solution for handling the audio.

So, it is B only

In real world, we would run transcribe first to convert the call to searchable text, and then run Comprehend to search and analyze for specific key words. Since the question is around analyize and extract key info, I will go for "D"
